Subject: Phase II Soil Investigation Report for the Jervis B. Webb Company Property at 5030 Firestone Boulevard in South Gate, California (EKI 961025.02)

Dear Mr. Stanesa:

Erler & Kalinowski, Inc. ("EKI") is pleased to submit this *Phase II Soil Investigation Report* ("Assessment") for the Jervis B. Webb Company of California ("Webb") property at 5030 Firestone Boulevard in South Gate, California ("Subject Property"). This Assessment was prepared in accordance with the Agreement, dated 25 November 1997, between Webb and EKI.

Limitations of Assessment

The conclusions and recommendations presented in the attached Assessment are our professional opinion and are not a warranty or guaranty as to the presence, absence, or extent of contamination at the Subject Property or of releases from or near the Subject Property. The facts presented in the Assessment are based on available information obtained by EKI and represent existing conditions at the Subject Property at the time the information was collected. This Assessment is intended for the sole use of Webb. Unless specifically authorized by EKI, and subject to execution of an agreement between EKI and any third party in a form and content approved by EKI, use or reliance by any other entity is not permitted or authorized.

Please call if you have any questions.

Very truly yours,

ERLER & KALINOWSKI, INC.

Steven G. Miller, P.E. (Civil Engineer, Certificate 43419)
Project Manager

1. EXECUTIVE SUMMARY

Erler & Kalinowski, Inc. ("EKI") was retained by the Jervis B. Webb Company ("Webb") to perform a series of environmental investigations of the property at 5030 Firestone Boulevard in South Gate, California ("Subject Property"). The *Phase II Soil Investigation Report* summarizes investigations of the Subject Property completed by EKI through December 1997. A brief summary of the major findings of EKI's investigations at the Subject Property follows:

1. The Subject Property consists of a single parcel of land approximately 1.4 acres in size and contains one single-story former manufacturing building of approximately 20,000 square feet. The property was apparently developed between 1950 and 1953.

2. Blake Rivet Company ("Blake") manufactured aircraft rivets at the Subject Property from the 1950s until approximately 1980. Blake's manufacturing process at the Subject Property included an above ground anodizing operation that generated wastewater. Wastewater was discharged, pursuant to a permit, to a three-stage clarifier and then to the sanitary sewer. Blake apparently stored a number of raw materials at the Subject Property including metal stock and anodizing solutions. Documents available to EKI did not identify historical use or storage of chlorinated organic solvents at the Subject Property.

3. Following Blake, Webb used the Subject Property for storage of metal stock, equipment and other materials. The concrete area at the location of the clarifier was also used by Webb for temporary storage of drums of hazardous wastes. The clarifier was not used by Webb. EKI completed an initial inspection of the Subject Property on 10 April 1996. No drums or significant staining of concrete or asphalt around the clarifier was observed by EKI during the site inspection. Currently, the property is unoccupied and has been cleared of all equipment and materials. The clarifier is currently filled with sand.

   Webb manufacturing operations were primarily located on the adjacent off-site property at 9301 Rayo Avenue ("Rayo Property"). Webb's activities at 9301 Rayo Avenue included metal fabrication, finishing, painting and assembly operations associated with the manufacture of industrial conveyor systems.

4. EKI observed indications of below ground concrete structures at several locations in the building. These include a concrete-lined sump and a shallow concrete-lined machine trench. The concrete floor in the building contains numerous patches where former structures or improvements may have been located. Concrete in the former anodizing area of the building is pitted, etched, broken and or cracking in several areas.

5. On 28 October 1997, Vironex, Inc. ("Vironex") of El Segundo, California completed fourteen soil borings at the Subject Property. The objective of the soil investigation was to provide chemical data to determine whether chemical releases occurred in former chemical use and storage areas at the Subject Property. Soil was cored to maximum depths ranging from approximately 10 feet below ground surface ("ft bgs") at various locations inside and outside the building, and to 20 ft bgs in the immediate vicinity of the clarifier. Soil samples were analyzed for pH by EPA Method 9045, total extractable petroleum hydrocarbons ("TEPH") by EPA Method 8015 modified, California Code of Regulations Metals ("CCR-Metals"), and volatile organic compounds ("VOCs") by EPA Methods 8240 and 8010.

6. Fourteen soil samples were analyzed for CCR metals. CCR metals were not detected at elevated concentrations in soil samples collected from beneath and around the clarifier and from other former process areas. Only one of the fourteen analyses for metals had a detectable concentration of hexavalent chromium, sample B4-10.5 had a concentration of 0.88 milligrams per kilogram ("mg/kg"). Samples of soil from above and below sample B4-10.5 (samples B4-6 and B4-16) did not have detectable hexavalent chromium.

7. TEPH was not detected in any of the ten soil samples analyzed for it. Soil pH was found to range from 6.3 to 8.8 in the samples analyzed.

8. VOCs were detected in samples of soil collected during the October 1997 soil investigation. Trichloroethene ("TCE") and tetrachloroethene ("PCE") were detected at maximum concentrations of 270 mg/kg and 140 mg/kg, respectively, in one soil sample (B4-20.5) collected from approximately 20 ft bgs beneath the clarifier. TCE and PCE were detected in most of the soil samples collected during October 1997 in the area of the former anodizing operations and, except for samples from boring B4, were detected at concentrations of less than 1 mg/kg. No other VOCs were detected.

9. On 1 and 2 December 1997, Interphase, Inc. ("Interphase") of Commerce, California completed a soil gas survey at the Subject Property. The objective of the soil gas survey was to provide additional subsurface data to identify potential source areas for the VOCs detected in samples of soil collected during the October 1997 investigation. Soil gas samples were collected from 37 separate locations at a depth of approximately 5 ft bgs and analyzed for 23 VOCs consistent with California Regional Water Quality Control Board - Los Angeles Region ("RWQCB") Primary Target Compounds.

   The analytical data from the soil gas survey indicated that TCE and PCE are the primary chemicals of concern in shallow soil at the Subject Property. TCE was detected at concentrations ranging from 0.074 micrograms per liter ("ug/L") to 25 ug/L. PCE was detected at concentrations ranging from 0.021 ug/L to 28 ug/L. 1,1,1-Trichloroethane ("1,1,1-TCA") was also detected at low concentrations in approximately half of the soil gas samples with a maximum of 0.89 ug/L.

Chloroform, dichlorodifluoromethane ("Freon-12"), and trichlorofluoromethane ("Freon-11") were also detected in a few samples at low concentrations.

10. On 2 and 3 December 1997, West Hazmat Drilling Corporation ("West Hazmat") of Anaheim, California completed five deep soil borings at the Subject Property. The purpose of the deep soil investigation was to determine the vertical extent of VOC occurrence in unsaturated soil beneath the clarifier and anodizing area. Soil borings were completed to maximum depths ranging from 46.5 to 62.5 ft bgs. Groundwater was encountered at a depth of approximately 57 ft bgs. Soil samples were analyzed for VOCs by EPA Method 8010. Additional soil samples were analyzed for geotechnical properties.

11. TCE and PCE were detected in samples of soil collected during the December 1997 investigation. TCE was detected at concentrations ranging from 0.048 mg/kg to 16 mg/kg. PCE was detected at concentrations ranging from 0.026 mg/kg to 0.66 mg/kg. TCE was detected in the deepest soil samples collected from each boring completed during the December 1997 investigation at concentrations ranging from 1.3 mg/kg to 8.7 mg/kg.

12. During the December 1997 investigation, twelve soil samples were selected for geotechnical analyses including total carbon by the Walkley-Black method, moisture content by ASTM Method D2216, dry density by ASTM Method D2937, and effective permeability and air conductivity by API Method RP40. The soil samples analyzed for geotechnical properties were selected to represent most of the geologic materials encountered in the vadose zone. Analytical results indicate significant soil moisture and total carbon concentrations in the vadose zone. Moisture content ranged from 7% to 39.9%. Total organic carbon ranged from not detected to a concentration of 1.11%. Dry soil density ranged from 82.8 pounds per cubic foot ("pcf") to 112.8 pcf. Of twelve samples analyzed for air conductivity and effective permeability, six samples did not conduct air.

On the basis of the results of investigations conducted to date it appears that further actions are necessary to address the presence of VOCs in the subsurface at the Subject property.

3. DESCRIPTION OF SUBJECT PROPERTY

3.1. Location and Size of Subject Property

The Subject Property is located at 5030 Firestone Boulevard in South Gate, California (see Figure 1, USGS, 1964). The Subject Property is bounded to the northwest by Firestone Boulevard. To the east and southeast are commercial/industrial properties. To the south and southeast is the 9301 Rayo Avenue property ("Rayo Property") that was also formerly occupied by Webb. Along the southwest side of the Subject Property are Union Pacific railroad tracks. An easement containing a large underground storm drain is located along the westerly side of the Subject Property. The Subject Property is approximately 1.4 acres in size (Webb, 1995).

3.2. Current Site Features

The Subject Property contains a single-story, former manufacturing building. The building occupies an area of roughly 20,000 square feet (Webb, 1995). The roof of the building contains several vents of various dimensions. The floor of the building consists of a concrete slab of variable thickness. The locations of key site features are shown on Figure 2. A more detailed description of current site conditions is provided in the summary of site background information in Appendix A.

The area around the building is covered with asphalt or concrete except for a planted area at the north end of the building. An out-of-service railroad spur passes through the west side of the parcel toward the southern boundary of the Property. A large underground storm drain passes through the Subject Property approximately parallel to the western property line and proceeds to the southeast through the Rayo Property. A utility line which EKI believes to be a sanitary sewer pipeline crosses the eastern side of the Subject Property and proceeds through the Subject Property toward the Rayo Property where is apparently discharges to a sewer line in Rayo Avenue. Former electrical and telephone service enter the property via overhead lines extending into the property also from the northeast. No pole-mounted or other transformers were observed within the property. A natural gas meter was observed on the southeast side of the building. The entrance to the Subject Property from Firestone Boulevard has been temporarily fenced. Access to the property is currently through the adjacent property located at 9301 Rayo Avenue.

3.3. Historical Site Use and Agency Records Reviews

EKI has reviewed documents provided by Webb, historical aerial photographs, and selected regulatory agency files. A summary of site background information obtained from EKI's review of these documents is provided in Appendix A.

4. REGIONAL HYDROGEOLOGICAL CONDITIONS

Unless otherwise noted, the information provided in this section was obtained from the California Department of Water Resources ("DWR") *Bulletin No. 104: Planned Utilization of the Groundwater Basins of the Coastal Plain of Los Angeles County, Appendix A, Groundwater Geology* dated June 1961.

The Subject Property is located in the Central Basin Pressure Area of the Central Basin of the Coastal Plain of Los Angeles County. Ground surface elevation at the Subject Property is roughly 110 feet above mean sea level (USGS, 1964). The surface topography of the Subject Property and vicinity appears to slope gently to the southeast in the general direction of the Los Angeles River. The Los Angeles River is located approximately 1,200 feet east of the Subject Property at its nearest location (see Figure 1, DWR, 1964).

The Subject Property is located within the Downey Plain, an alluvial depositional feature of Recent age that extends across the central lowland areas of the Central Basin. Depositional materials associated with this feature were deposited as alluvial fans formed by the Los Angeles and Rio Hondo-San Gabriel River systems. These alluvial systems have formed a very gentle plain. However, during past flood times these large rivers have produced some erosional terraces and deposited debris over most of the area. The materials associated with the Downey Plain are also referred to as Recent Alluvium. Little deformation of the Recent alluvial sediments has occurred except where they cross techtonically active areas.

The Subject Property is located along the northern axis of the Paramount Syncline, a depressional deformation feature trending northwest-southeast in the vicinity of the Subject Property. This structure was formed by the Early Pleistocene deformation of the Central Basin. The trough-shaped geometry of this structure has produced folding of Early Pleistocene deposits of primarily the Lakewood and San Pedro Formations. According to DWR, no displacement of aquifers is apparent in the vicinity of the Subject Property.

The water-bearing materials composing the groundwater basin in the vicinity of the Subject Property are Recent to Pliocene in age. These materials include unconsolidated and semi-consolidated marine and non-marine alluvial sediments. Sizes of individual particles grades from course gravel and boulders to clay. Following is a description of the major aquifers that comprise the groundwater basin in the vicinity of the Subject Property.

4.1. Regional Aquifers

The area of the Subject Property is underlain by several major hydrostratigraphic units within three geological formations: the Recent Alluvium, Lakewood Formation and San Pedro Formation. In the vicinity of the Subject Property the Recent Alluvium is present from surface elevation (110 feet above mean sea level "ft. msl") to approximately 20 to 80 ft bgs. The Recent Alluvium is apparently comprised of the Bellflower Aquiclude and Gaspur Aquifer. However, it is apparent that the Gaspur Aquifer may be partially or completely absent in the immediate vicinity of the Subject Property. In the absence of the Gaspur aquifer, an unnamed confining layer of the Lakewood Formation would compose a portion of the subsurface materials between 20 and 80 ft bgs. (Plates 6A and 6E, DWR, 1961).

The first aquifer in the vicinity of the Subject Property appears to be the Exposition Aquifer of the Lakewood Formation. The Exposition Aquifer reportedly begins at about 80 to 90 feet below ground surface and is roughly 100 to 120 feet thick. Underlying the Exposition Aquifer is an unnamed confining layer that may be present in substantial thickness in the vicinity of the Subject Property. Beneath the unnamed confining layer and/or Exposition Aquifer is the Gage Aquifer which is also part of the Lakewood Formation. The Gage Aquifer appears to begin at approximately 220 to 300 ft bgs, depending on the thickness of the unnamed confining layer, and is roughly 50 to 90 feet thick.

Beneath the Lakewood Formation is the San Pedro Formation which consists of, in descending order, a significant unnamed aquiclude, Jefferson Aquifer, Lynwood Aquifer, Silverado Aquifer, and Sunnyside Aquifer. The Jefferson, Lynwood and Silverado aquifers range in thickness from 80 to 250 feet thick in the vicinity of the Subject Property and may be interbedded by minor confining layers. The base of the Silverado Aquifer is approximately 930 to 950 ft bgs. The Silverado and Sunnyside Aquifers are interbedded by an unnamed confining layer approximately 260 to 340 feet in thickness. The Sunnyside Aquifer is 300 feet thick in the vicinity of the Subject Property. (Plates 6A and 6E, DWR, 1961).

Underlying the San Pedro Formation are the Pliocene marine sediments of the Pico Formation. Although portions of the Pico Formation may be sufficiently permeable to transmit water, the water is of poor quality and unsuitable for general use.

4.2. Regional and Local Groundwater Flow

According to the Water Replenishment District of Southern California ("WRD"), deep aquifer groundwater contours for water year 1995-1996 indicate southwesterly trending groundwater flow from the Whittier Narrows area into the Central Basin Pressure Area with a gradient of approximately 0.007 feet per foot. Depth to groundwater in the vicinity of the Subject Property is indicated to be approximately 80 to 90 ft bgs. (WRD, 1997)

Based on groundwater monitoring data from the Dial Corporation site, across Rayo Avenue and several hundred feet southeast of the Subject Property, groundwater flow is in a southerly direction at a gradient of approximately 0.003 feet/foot. The depth to groundwater in two monitoring wells located along Rayo Avenue ranged from about 45 to 55 ft bgs from April 1992 to April 1995. One well on the Dial Corporation site was found to have shallower perched groundwater (EMCON, 1995). Bechtel, however, reported that groundwater flow in the "upper group of aquifers" is to the north-northwest. (Bechtel 1994, page 6)

Actual depth to groundwater at the Subject Property was found to be approximately 57 ft bgs at the southeasterly boundary during investigations by EKI. The direction of groundwater flow in the water table aquifer beneath the Subject Property has not been determined.

5. SUBSURFACE INVESTIGATIONS

On 28 October 1997, Vironex, Inc. ("Vironex") of El Segundo, California, completed fourteen soil borings at the Subject Property to maximum depths ranging from 10 to 20 ft bgs. The objective of this soil investigation was to determine if chemicals of concern are present in soil at the Subject Property. Soil samples were analyzed for pH using EPA Method 9045, California Code of Regulation Metals ("CCR-Metals"), total extractable petroleum hydrocarbons ("TEPH") using EPA Method 8015 modified, and volatile organic compounds ("VOCs") using EPA Methods 8260 and 8010.

On 1 and 2 December 1997, Interphase, Inc. ("Interphase") of Commerce, California completed a soil gas survey at the Subject Property. The objective of the soil gas survey was to provide additional subsurface data to identify potential source areas for VOCs detected in soil collected during the October 1997 investigation. Soil gas samples were collected from 37 separate locations at a depth of approximately 5 ft bgs. Soil gas samples were analyzed for 23 VOCs in accordance with the RWQCB's Well Investigation Program ("WIP") Primary Target Compounds list.

On 2 and 3 December 1997, West Hazmat Drilling Corporation ("West Hazmat") of Anaheim, California completed five deep soil borings at the Subject Property. The purpose of the deep soil investigation was to provide additional data for characterization of the distribution of VOCs in the vadose zone and soil geotechnical properties. Soil borings were completed to maximum depths ranging from 46.5 to 62.5 ft bgs. Groundwater was determined to be present at a depth of approximately 57 ft bgs. Soil samples were analyzed for VOCs using EPA Method 8010.

The locations of soil borings and soil gas sampling locations at the Subject Property are shown on Figure 3. Field and analytical procedures performed during the investigations are described below. Analytical results for the soil gas survey and soil investigations are summarized below and provided in Tables 1 and 2, respectively. Results of soil geotechnical testing are summarized in Table 3. Contours of VOC concentrations detected in shallow soil gas are presented on Figures 4 through 6. Analytical results for soil sampling are presented on Figures 7 and 8. Boring logs containing lithologic descriptions of soil and depths of soil samples retained for analyses are provided in Appendix B. A complete report by Interphase, describing soil gas survey procedures and analytical data, is provided in Appendix C. Laboratory analytical data and Chain-of-Custody forms for soil samples are attached in Appendix D. Laboratory data and Chain-of-Custody forms for soil geotechnical testing are attached in Appendix E.

5.1. Field Procedures

5.1.1. Geophysical Surveys

EKI contracted with Spectrum Environmental Services, Inc. of San Fernando, California to conduct subsurface geophysical surveys of utilities located near each proposed drilling location at the Subject Property. Spectrum performed geophysical surveys on 24 October 1997 and 1 December 1997. Underground Services Alert ("USA" or Dig Alert) was notified 48-hours prior to the commencement of ground penetrating activities on 28 October 1997 and 1 through 3 December 1997.

5.1.2. Shallow Soil Boring Investigation

Coring of soil beneath the Subject Property on 28 October 1997 was performed by Vironex. EKI performed lithologic logging and selection of soil samples for chemical analysis and geotechnical testing. Soil lithologic classification was performed in accordance with the Unified Soil Classification System ("USCS"). Soil color descriptions were graded according to Munsell Soil Color Chips. Soil boring logs were approved by Ms. Beth Lamb, R.G., C.E.G., C.H., a State of California registered geologist. (see Appendix B)

Fourteen soil borings (B1 through B14) were completed as part of the October 1997 soil investigation (see Figure 3). Eleven soil borings were located in the central and southerly portions of the Property near the location of the clarifier, the former anodizing area, the former furnace pit, and near several suspected underground structures (described in Section 3.6.2.). Two additional soil borings (B12 and B13) were located in the northwest corner of the building in the former wire storage/receiving area, where additional concrete patches were observed by EKI. A final soil boring (B14) was installed in the parking lot north of the building for the purpose of collecting background soil samples for potential analysis of CCR-Metals pending results for soil samples collected in the former anodizing and clarifier areas. Samples from boring B14 were not analyzed.

Soil samples retained during the October 1997 soil investigation were collected from approximately 5-feet intervals from depths ranging from 2 ft bgs to 20 ft bgs. Soil borings B2, B3, and B5 through B14 were completed to approximately 10 ft bgs. Soil borings B1 and B4, located adjacent to the clarifier, were completed to approximately 20 ft bgs. Because the clarifier is located within an exterior building corner with limited access, borings B1 and B4 were situated at the nearest safe working distance to the clarifier. Boring B4 was installed at an angle of approximately 15 degrees from vertical to access soil beneath the clarifier at the maximum specified depth of 20 ft bgs.

Soil borings were completed using a Vironex half-ton truck with a Geoprobe sampling probe ("Soil probe"). The Soil probe utilized a 2-feet long by 1.5-inch outer diameter soil sampler and 1.5-inch outer diameter probe sections. The soil sampler, containing four pre-cleaned, 6-inch brass liners, was driven approximately 24 inches into undisturbed soil at each sampling interval, then retrieved and disassembled. One or two sample liners

were retained for laboratory chemical analysis at each sampling interval. Remaining sample liners were utilized for soil lithologic classification. Soil samples that were not retained for laboratory testing were placed into a DOT-approved 35-gallon drum for later disposal.

Soil sample liners retained for laboratory chemical analysis were removed from the sampler and separated with a clean knife. The ends of the brass tube containing the each sample were covered with Teflon sheets and capped with plastic end caps. A sample label that included a unique sample identification number, the sample depth, the time, and the date when the sample collected was attached to each brass liner. Samples to be delivered to the laboratory for chemical analysis were sealed in zip-lock plastic bags and placed in a cooler with ice for temporary storage and transport to the laboratory. Chain-of-Custody forms were initiated in the field and included with the samples. Chain-of-Custody Forms are included in Appendix D.

All downhole pieces of the soil boring and sampling equipment were decontaminated prior to their use and between sample locations. Between sampling intervals, the soil sampling tool and brass sample liners were cleaned in an Alconox solution, then rinsed in potable and distilled water. The rinse water generated during decontamination was contained on-site.

5.1.3. Soil Gas Survey

Soil probe installation and soil gas sample collection on 1 and 2 December 1997 was performed by Interphase. EKI observed soil boring installation and soil gas collection procedures and documented the work. The soil gas survey was performed in accordance with RWQCB guidelines for active soil gas investigations under the Well Investigation Program, dated February 1997. Sample analyses included the RWQCB's Primary Target Compounds list of 23 VOCs. Interphase procedures for soil gas sample collection are described in the Interphase Soil Gas Survey Report in Appendix C.

Thirty-seven shallow soil borings (SG1 through SG37) were completed for collection of soil gas samples (Figure 3). Soil gas sampling locations were situated in positions surrounding suspected source areas in the central and southerly portions of the building near the location of the clarifier, the former anodizing area, the former furnace pit and several suspected underground structures. Additional soil gas sampling locations were positioned near the boundaries of the Subject Property and areas outside the former manufacturing building. Soil gas samples were collected from approximately 5 ft bgs, except at three locations (SG29 through SG31) where refusal was encountered at 2 to 3 ft bgs.

Soil borings for soil gas sample collection were completed using an Interphase van equipped with a Soil probe. The soil probe utilized a 2-feet long by 1.5-inch outer diameter soil gas sampler attached to 1.5-inch outer diameter probe sections. No drill cuttings were generated during the soil gas survey. Interphase soil gas sample collection

methods and sampling apparatus are described in the Interphase Soil Gas Survey Report in Appendix C.

All downhole pieces of the soil boring and sampling equipment were decontaminated prior to their use and between sample locations and distinct sampling depths. Between sampling intervals, the soil probes were cleaned in an Alconox solution, then rinsed in potable and distilled water. The rinse water generated during decontamination was contained on-site in a DOT-approved 55-gallon drum for later disposal.

5.1.4. Deep Soil Boring Investigation

Additional soil coring and sampling was performed on 2 and 3 December 1997 by West Hazmat. EKI performed lithologic logging and soil sample selection for chemical analyses and geotechnical testing. Soil sample handling and soil lithologic characterization was performed in accordance with procedures described in Section 5.1.2. Boring logs are provided in Appendix B.

Five soil borings (B15 through B19) were completed as part of the December 1997 soil investigation (Figure 3. Three soil borings (B15 through B17) were located at positions at a lateral distance of approximately 50 feet surrounding the clarifier. Soil borings B18 and B19 were positioned at locations adjacent to the clarifier.

Soil samples retained during the December 1997 soil investigation were collected from several depth intervals. Soil boring B15, situated to the northwest of the clarifier, was completed to approximately 52.5 ft bgs using continuous core sampling with a Soil probe. The remaining soil borings were installed using a hollow-stem auger. Soil boring B16, situated to the south of the clarifier, was completed to approximately 51.5 ft bgs. Soil samples were collected at approximately 5-feet intervals from at location B16. Soil boring B17, located to the southeast of the clarifier, was completed to approximately 62.5 ft bgs.
After advancing soil boring B17 to total depth at 62.5 ft bgs, West Hazmat lowered a water level indicator through the auger casing. The groundwater surface was present at a depth of approximately 56.9 ft bgs. Soil samples were collected at approximately 2.5-feet intervals at location B17. Soil borings B18 and B19 were completed to approximately 46.5 ft bgs. Soil samples were collected at approximately 5-feet intervals at locations B18 and B19.

Soil borings were completed using a West Hazmat track-drive limited access rig ("LAR"). The LAR was equipped with a soil sampling probe and a hollow-stem auger. The Soil probe utilized a 2-feet long by 2-inch outer diameter soil sampler and 2-inch outer diameter probe sections. Drill cuttings generated with the use of the Soil probe were placed into a DOT-approved drum already present on-site. Hollow-stem auger drilling was completed using 8.25-inch outer diameter augers. Soil sample collection during auger drilling was accomplished using a California-modified, 2-feet long by 2-inch outer diameter soil sampler. Soil cuttings generated using the hollow-stem auger method were placed in DOT-approved 55 gallon drums for later disposal.

All downhole pieces of the soil boring and sampling equipment were decontaminated prior to their use and between sample locations. Between sampling intervals, the soil probes or auger casings were steamcleaned using a West Hazmat mobile decontamination trailer. Soil sampling tools and brass sample liners were cleaned in an Alconox solution, then rinsed in potable and distilled water. The rinse water generated during decontamination was contained in DOT-approved, 55-gallon drums for later disposal.

5.2. Summary of Soil Gas Survey Results

5.2.1. Analytical Results for Soil Gas Survey

Soil gas samples were analyzed by Interphase in a mobile laboratory situated inside the Interphase van. Soil gas samples were analyzed using gas chromatographic techniques. For a complete description of analytical methods and instrumentation used for the soil gas survey, please refer to the Interphase Soil Gas Survey Report in Appendix C.

The analytical results for soil gas samples are summarized in Table 1 and graphically on Figures 4 through 6. TCE, PCE, 1,1,1-TCA, chloroform, dichlorofluoromethane ("Freon-12") and trichlorofluoromethane ("Freon-11") were detected in soil gas samples. TCE and PCE were detected in most soil gas samples analyzed. 1,1,1-TCA was also detected at low concentrations in approximately half of the soil gas samples.

Concentrations of TCE detected in samples of shallow soil gas ranged from 0.13 ug/L to 25 ug/L. As shown on Figure 4, the highest concentrations of TCE were detected in samples of soil gas collected in the southeast corner of the Subject Property. The highest soil gas detection of TCE was from the sample collected from location SG36, located at the boundary of the Subject Property (Figure 3). Soil gas samples collected from points immediately surrounding the clarifier were found to contain TCE at concentrations ranging from 3.9 ug/L at location SG3 to 13 ug/L at location SG10.

Concentrations of PCE detected in samples of shallow soil gas ranged from 0.021 ug/L to 28 ug/L. As shown on Figure 5, the highest concentrations of PCE were detected samples of soil gas collected in the southeast corner of the Subject Property. The highest soil gas detection of PCE was from the sample collected from location SG10, located approximately 10 feet northeast of the anodizing area trench (Figure 3). Soil gas samples collected from points in the clarifier area were found to contain PCE at concentrations ranging from 1.6 ug/L at location SG3 to 28 ug/L at location SG10 (Figure 3).

Concentrations of 1,1,1-TCA were detected in approximately half of the soil gas samples collected. Concentrations of 1,1,1-TCA detected in samples of soil gas ranged from 0.013 ug/L at location SG6 to 0.89 ug/L at location SG22, located adjacent to the furnace pit area. As shown on Figure 6, the highest concentrations of 1,1,1-TCA in soil gas appear to be centered in the southeast corner of the Subject Property.

Chloroform, dichlorofluoromethane ("Freon-12") and trichlorofluoromethane ("Freon-11") were also detected at low concentrations in several soil gas samples. Chloroform was detected at concentrations ranging from 0.038 ug/L to 0.058 ug/L in soil gas samples from locations SG1, SG9, SG10, SG14, SG22 and SG36 (Figure 3). Freon-11 was detected in soil gas samples from locations SG22 and SG33 at concentrations of 0.010 ug/L and 0.032 ug/L, respectively. Freon-12 was detected at a concentration of 1.2 ug/L in soil gas at location SG33.

Interphase collected a duplicate sample from location SG23 for off-site compound confirmation analysis by EPA Method TO-14 at an independent laboratory. This sample was analyzed by Environmental Analytical Service, Inc. ("EAS") of San Luis Obispo, California. Results of the duplicate sample analysis by EAS are discussed below.

5.2.2. Quality Assurance/Quality Control for Soil Gas Survey

Quality Assurance/Quality Control ("QA/QC") for the Soil Gas Survey is discussed in detail in the Interphase Soil Gas Survey Report in Appendix C. For the survey, Interphase collected a system blank and ambient air sample prior to sample collection each day. As discussed above, one duplicate sample was collected and analyzed at an independent laboratory. Additional QA/QC procedures included a purge volume versus analyte concentration test at the first soil gas sampling location and mid-point calibration checks. The percent relative deviation of the mid-point calibration checks were within WIP QA/QC guidelines.

The compound confirmation sample analyzed by EAS confirmed the compounds detected by Interphase. In addition, EAS detected methylene chloride, styrene, toluene and xylenes in the sample. However, the additional compounds detected by EAS were detected at concentrations which are near or below Interphase's reporting limits for these compounds.

5.3. Summary of Soil Sampling Results

5.3.1. Analytical Results for Soil Sampling

The analytical results for soil samples are summarized in Table 2, 3, 4 , and 5. Concentrations of PCE and TCE detected in soil are also summarized on Figures 7 an 8. Laboratory analysis reports with Chain-of-Custody Forms are attached in Appendix D.

Soil samples collected during the 28 October 1997 soil investigation were analyzed by Orange Coast Analytical, Inc. ("Orange Coast") of Tustin, California for pH by EPA Method 9045, TEPH by EPA Method 8015 modified, CCR-Metals, and VOCs by EPA Methods 8240 and 8010. Soil samples collected during the 2 and 3 December 1997 soil investigation were analyzed by Orange Coast for VOCs using EPA Method 8010.

Nine soil samples collected from locations adjacent to the clarifier and former process areas were analyzed for pH. The analytical results for these analyses indicate that soil pH values ranged from 6.3 to 8.8. The results of pH analyses are summarized in Table 3.

Of ten soil samples analyzed for TEPH, none were found to contain TEPH above method detection limits. See Table 4 for a summary of these analyses.

Fourteen soil samples were analyzed for CCR-Metals. One soil sample was found to contain hexavalent chromium at a concentration of 0.88 milligrams per kilogram ("mg/kg"). However, no other soil samples had detectable hexavalent chromium. Metals concentrations appeared to be within acceptable ranges and indicative of indigenous concentrations in soil. Results of metals analyses are summarized in Table 5.

TCE and PCE were the only VOCs were detected in samples of soil collected during the October and December 1997 soil boring investigations. TCE and PCE were detected at maximum concentrations of 270 mg/kg and 140 mg/kg in one soil sample (B4-20.5) collected from approximately 20 feet below ground surface ("ft bgs") beneath the clarifier. At surrounding sampling locations, VOCs concentrations in soil samples typically ranged from 0.003 mg/kg to 0.13 mg/kg. Results of VOC analyses are summarized in Table 5 and in Figures 7 and 8.

Analytical results for soil samples collected during the December 1997 soil investigation indicate that TCE and PCE were detected in deep vadose zone soil to a depth of at least 53.5 ft bgs. Soil samples collected from each of the five deep soil borings (B15 through B19) at a depth of approximately 46 ft bgs had detected concentrations of TCE ranging from 1.3 mg/kg to 8.7 mg/kg. Concentrations of PCE detected in soil collected at 46 ft bgs were significantly lower, ranging from non-detect to 0.18 mg/kg at B18 and B19.

5.3.2. Quality Assurance/Quality Control for Soil Chemical Analyses

Standard laboratory QA/QC procedures used for the project included method blanks and matrix spikes/matrix spike duplicates. Percent recovery matrix spikes and matrix spike duplicates was within acceptable ranges. No detections were found in method blanks analyzed for the project. QA/QC results are provided with the laboratory reports in Appendix D.

5.3.3. Soil Geotechnical Testing Results

Twelve soil samples were selected for geotechnical analyses. These analyses were performed to provide data for a possible future fate and transport modeling or evaluation and design of remedial alternatives. The soil samples selected for geotechnical testing were chosen from depths and lithologies considered generally representative of the various geologic materials present in the vadose zone. Geotechnical analyses included total organic carbon by the Walkley-Black method, moisture content by ASTM Method D2216, dry density by ASTM Method D2937, and effective permeability and air

conductivity by API Method RP40. See Table 3 for results of geotechnical testing. Laboratory data sheets and Chain-of-Custody forms are attached in Appendix D.

As shown in Table 6, moisture content ranged from 7 to 39.9 percent and total organic carbon ranged from 0.10 to 0.96 percent. Of twelve samples analyzed for air conductivity and effective permeability, six samples did not conduct air. The remaining soil samples had effective permeabilities ranging from 0.4 millidarcies to 1246.4 millidarcies. Comparable air conductivity results for these samples ranged from 5.2×10^{-7} to 8.2×10^{-5}. The sample with the highest air permeability corresponds to a thin bed of well-graded fine to medium grained sand at a depth of 36 ft bgs from soil boring B16. Only one soil sample (B16-16.5) collected from the shallow vadose zone was found to have measurable air conductivity properties. The remaining samples of soil that exhibited measurable air flow were collected from depths of 36 to 46 ft bgs.

5.3.4. Characterization of Vadose Zone Soils

Soil present in the vadose zone beneath the Subject Property are predominantly silts with variable clay and sand content. However, clay and sandy soils are also present. The vadose zone is characterized by interbedded clayey, silty and sandy beds which appear to be lenticular but largely continuous in structure over the investigation area. These sediments are probably associated with the Downy Plain alluvium as discussed in Section 4. Due to the nature of deposition of these sediments, stream channel and overbank splay deposits associated with the Quaternary fluctuations of Los Angeles River, it is possible that the structure and presence of various lithologies in the vadose zone is variable laterally as well as vertically in the immediate area of the Subject Property.

Several recognizable lithologies were observed to be present in all five borings. In particular, a moderately to highly plastic clay unit of variable thickness ranging from approximately 1 to 5 feet was observed at depths of approximately 24 to 26 ft bgs in all five deep soil borings (borings B15 to B19). This unit appears to be thinner in the vicinity of soil borings B18 and B19. The clay unit is overlain and underlain by silty materials. A pronounced sandy unit was observed in all five borings at a depth of approximately 34 to 36 ft bgs. This unit also varies in thickness, ranging from approximately 1 to 4 feet thick. See Figures 9 and 10 for an illustration of vadose lithology at the subject property. Boring logs are attached in Appendix B.

6. FINDINGS

6.1. Chemicals of Concern

EKI's investigations included sampling and analysis of soil gas for VOCs and soil for VOCs, metals, pH and TEPH. On the basis of the analyses completed it appears that VOCs, specifically TCE and PCE, are present in the vadose soil at the Subject Property at concentrations which warrant further investigation. Other chemicals do not appear to warrant further investigation.

6.2 Potential Source Areas

The clarifier and former anodizing operation area appears to be the location of past releases of TCE and PCE. The highest VOC concentrations were detected in the general area of the clarifier and former anodizing operations. The soil sample (B4-20.5) with the highest TCE and PCE concentrations was collected beneath the clarifier. Based on sampling results, no other significant potential source area was identified.

6.3 Distribution of TCE and PCE in Vadose Soil

Concentrations of TCE and PCE detected in shallow soil were relatively low compared to concentrations of these chemicals detected in deeper soil samples. Both TCE and PCE were detected in most of the shallow soil samples collected in the area of the clarifier and former anodizing operations. The highest concentrations of TCE and PCE detected in soil samples from 11 ft bgs or less were 0.11 mg/kg and 0.40 mg/kg, respectively, both in sample B18-11 next to the clarifier.

The highest concentrations of TCE and PCE detected at the site were in deep soil samples (between 20 ft bgs to 46 ft bgs) from borings B4, B18, and B19 next to the clarifier. The highest concentration of each was detected in soil sample B4-20.5 beneath the clarifier with TCE at 270 mg/kg and PCE at 140 mg/kg. Concentrations of TCE were greater than 1 mg/kg in most of the soil samples analyzed between 20 ft bgs and 46 ft bgs at the clarifier (Figure 10). Concentrations of PCE were much lower in the same soil samples. None of the soil collected from below sample B4-20.5 had concentrations of PCE greater than 0.66 mg/kg.

There appears to have been lateral migration of TCE, and to a lesser extent also PCE, from the area of the clarifier. The deepest soil sample from each of the three perimeter soil borings B15, B16, and B17 (each located approximately 50 feet from the clarifier) was found to have a concentration of TCE greater than 1 mg/kg (B15-44.5, B16-53.5, and B17-46). PCE, however, was not detected in the deepest samples from the perimeter

borings. An approximation of the lateral distribution of TCE in soil at 20 and 40 ft bgs are shown on Figures 11 and 12, respectively.

The depth to groundwater was found to be approximately 57 ft bgs during these investigations. No groundwater sampling was performed.

6.4 Conclusions

On the basis of the results of investigations conducted to date it appears that further actions are necessary to address the presence of VOCs in the subsurface at the Subject property.

Appendix A

Site Background Information

SUMMARY OF SITE BACKGROUND INFORMATION

This attachment provides a summary of site background information from EKI's review of documents provided by Webb, historical aerial photographs, and regulatory agency files for 5030 Firestone Boulevard in South Gate ("Subject Property").

A.1 Description of Current Site Conditions

The Subject Property is not currently occupied except that the current owner/operator of the business at 9301 Rayo Avenue property uses portions of the Subject Property for storage of containerized raw materials and equipment. The locations of key site features are shown on Figure 2.

A.1.1 Exterior Areas

The areas along the northern and eastern sides of the Subject Property are covered with asphalt except for a vegetated area at the north end of the building. The area along the west side of the building is asphalt covered and an out-of-service railroad spur passes near the building. A fence bounds the property on the west, north, and east sides. The area south of the building is asphalt and concrete covered with open access to the Rayo Property. Unpaved areas are present beyond the southern boundary of the property. During EKI's initial site inspection, the areas outside of the building were generally clear of debris. Some minor refuse and automobile tires are present on the Subject Property. No significant waste materials have been observed during EKI's subsequent visits to the Subject Property.

Just outside an inset corner on the southeast side of the building, under an overhanging roof, is a three stage clarifier approximately 4-feet wide by 8-feet long in area (see Figure 2). Based on a detail shown on the Plumbing Plan, the clarifier is approximately 4-feet deep. The structure is set in a concrete pad that rises approximately six inches above the surrounding asphalt area. A sample collection box at the northeasterly end of the clarifier was observed to be filled with concrete. The main chambers of the structure were observed to be filled with sand and covered with steel plates. No plumbing for the clarifier was visible at the surface on the outside of the building. Following Blake, this area was later used by Webb for temporary storage of drums of hazardous materials before the drums were transported off-site for disposal. No drums or other materials were present at this location during the walk-through.

During recent investigation activities at the Property, a subcontractor, Cornerstone Environmental Contractors, Inc. of Walnut Creek, California was retained by Webb to remove a portion of the overhanging roof above the clarifier. This activity was required in order to access the clarifier area with a drill rig.

A.1.2 Inside Areas

No raw materials, equipment or waste have been observed by EKI inside the manufacturing building. Refuse, wood scraps and other materials associated with the aging building structure are present in small quantities. Following is a description of features of the building and associated former process and storage areas reportedly used by Blake during their activities at the Property.

As shown on the Plumbing Plan for Blake Rivets' waste discharge permit (City of South Gate Industrial Wastewater Discharge Permit No. 5181), the "anodizing area" is located on the southeast side of the building. An L-shaped floor drainage trench is present along the northeasterly and southeasterly walls bounding the anodizing area (see Figure 2). The trench is approximately 2-inches to 6-inches deep and slopes toward a drain at the southwest end of the trench. The trench drain leads underground to the clarifier on the exterior of the adjacent wall. The trench was observed by EKI to partially be filled with sandy gravel fill. The trench is in a location described on the Plumbing Plan as the "trench for all overflow water" and is indicated to have been 48-inches wide and 6-inches deep. Concrete in the area of the trench was observed to be severely etched. Concrete at other locations in the anodizing area was observed to be broken and/or cracked. EKI observed a 2-inch outer diameter pipe in the anodizing area next to the discharge point to the clarifier. This pipe extends from the southeasterly trench wall toward the ceiling and appears to have been a vent pipe for the clarifier.

Also in the southeast corner of the building, is an area indicated in the waste discharge permit to have had "rinse tanks." Numerous patches were observed by EKI in this area. The Plumbing Plan indicates that former structures in this area may have been associated with the former "trench for all overflow water." During the Phase II investigation, EKI observed that the roof in this area of the building had been constructed with wood braces for supporting a secondary wall that apparently extended down from the roof. This former feature may have been used to section-off the rinse tanks area from the other portions of the building.

Just west of the rinse tanks area is an area noted on Plumbing Plan as having a "concrete pit for furnace and quench tank." A floor drain is indicated to have been in the floor of the pit and the Plumbing Plan shows that it may have discharged to the sanitary sewer, located to the south of the building. No pit was observed in this location during the site walk-through; however, a large rectangular concrete patch was observed in the floor in the area. In the western portion of the building, EKI observed a 2-inch outer diameter pipe extending from the concrete floor toward the ceiling. Based on the location of the pipe, situated in the vicinity of a sewer line shown on the Plumbing Plan, it is apparent that the pipe may be a vent pipe for the sanitary sewer.

The Plumbing Plan identifies the middle portion of the building as the "machine area." Extending from the large bay entrance of the building to the northwest are two rows of machine anchor bolts in the concrete floor. It appears that these anchor bolts were associated with former machining equipment. Some small oil stained concrete areas were

observed by EKI. Electrical conduit for the former machinery was observed to be present in the concrete floor at numerous locations within the building.

In the central portion of the building, EKI observed a recessed portion of the concrete ("sump"). This structure is approximately 2 feet wide by 4 feet long and 6-inches deep. EKI inspected the inside of the structure and did not observe any pipes or other conveyance into or out of the structure. Because the structure was very shallow, it is not likely that the structure was used for liquid storage or conveyance.

The west side of the building is described on the Plumbing Plan as having been used as a wire storage and receiving area. Several concrete patches were observed in the northwestern corner of the building, which is indicated on the Plumbing Plan to have been a former "receiving area." This area was apparently used by Blake for receiving raw materials. Directly south of the receiving area is a general area that was formerly used for "wire storage."

The east side of the building is identified on the Plumbing Plan as having been used for storage and shipping. On the east corner of the building, EKI observed a concrete sump covered by a steel plate. This structure is approximately 2 feet wide by 4 feet long and was observed by EKI to be filled with sand. Concrete patches of approximately the same dimensions were also observed in the vicinity of the covered sump. Based on our inspection of the concrete patches in the area, it is possible that additional below ground structures were previously present at these locations. EKI did not establish the depth of the existing below ground structure or attempt to verify the presence any conveyance piping. This sump is not described on the Plumbing Plan.

The northeast area of the building formerly had plaster and wood interior build-outs that were used for offices, restrooms and a lunch room. These walls no longer exist. Some vinyl floor tile, ceramic floor tile, plumbing and a floor drain were observed by EKI in this area. The Plumbing Plan identifies one small room as a "lab." It is apparent that the floor drain was associated with the restrooms.

A.2 Historical Uses of the Subject Property

EKI has reviewed several documents provided by Webb and additional materials gathered by EKI to obtain historical use information for the Subject Property and surrounding area. Sources used to establish historical use of the Subject Property included historical aerial photographs obtained at Continental Aerial Photo, Inc. in Los Alamitos, California ("Continental") and Fairchild Aerial Photo Collection, Department of Geology, at Whittier College ("Fairchild"). EKI also reviewed historical maps from the Sanborn Mapping and Geographic Information Service ("Sanborn"). A brief discussion of historical use of the Subject Property, beginning with the earliest record reviewed, follows.

In 1928, the Subject Property was vacant. Several dirt roads appeared on the Subject Property and adjacent Rayo Property by 1932; however, there was no development of the

Subject Property through 1947 (Fairchild, 1928, 1932, 1947). By 1950, substantial industrial development was evident at properties adjacent to and in the vicinity of the Subject Property. However, no development of the Subject Property had occurred as of 1950 (Sanborn, 1950). In 1953, the Subject Property was developed with two small buildings, which consisted of separate portions of the current building configuration. The Rayo Property was still undeveloped in 1953 (Fairchild, 1953). In 1954, the Rayo Property was developed with a large manufacturing building (Continental, 1954). By 1957, the two separate buildings on the Subject Property had been joined by a large addition, consisting of the main manufacturing portion of the current structure (Fairchild, 1957). Additional expansion of buildings on the Subject Property and the Rayo Property had occurred by 1960 (Continental, 1960). The railroad spur located on the western side of the building on the Subject Property was present by 1966 (Sanborn, 1966). Few changes to the configuration of the Subject Property occurred from 1960 through 1992 (Continental, 1970, 1976, 1986, 1992).

A.3 Findings of Previous Site Assessments

According to Webb, Blake and Webb have been the only occupants of the Subject Property since development of the land between 1950 and 1953. It is our understanding that no sampling and analysis of soil or groundwater has been completed at the Subject Property prior to the recent investigations of the Subject Property.

EKI reviewed several documents provided by Webb relevant to environmental conditions at the Subject Property. Because Webb's activities at the Rayo Property included use of the Subject Property for miscellaneous materials and hazardous waste storage, a brief summary of information concerning Webb's operations and chemical used at the Rayo Property is also provided herein.

Hart Report. In 1988, Fred C. Hart Associates completed an environmental compliance assessment of Webb's current operations at 9301 Rayo Avenue and 5030 Firestone Boulevard. While Hart's assessment included the Subject Property, it appears that the Property was not used during Webb's operations for purposes other than storage of raw materials and drums of hazardous waste. The Hart Report did not identify any chemical use at the Subject Property.

On the Rayo Property, the report indicates that Webb operations included: "...metal fabrication (shearing, bending, sawing, machining, welding), painting operations and some assembly." (Hart, 1988, page 2)

Raw materials used included: "...I-beam stock, channel stock, plate and sheet metal, tubing, angle iron, paints and solvents." (Hart, 1988, page 2)

Solvent use was described as: "Solvents (J209 and Solvent Blend) are used as thinner/solvent for maintaining viscosity and for cleaning equipment. These solvents both are a mixture of alcohols, esters, ketones, toluene, xylene, glycol ethers and petroleum distillates in varying concentrations." (Hart, 1988, page 2)

Wastes generated included: "...waste paint, used solvent, waste oil and coolants, scrap metal and general trash." (Hart, 1988, page 2)

Several hazardous materials were used in the cleaning and painting activities, these included: "...solvents, oils and paints. Solvent, specifically 1,1,1-trichloroethane (1,1,1-TCA), was used for cleaning steel parts and products. The waste generated from the cleaning activities was containerized in 55- gallon drums and sent to an off-site treatment, storage, and disposal facility." (Hart, 1988, page 2)

Bechtel Report. Bechtel completed a Preliminary Assessment/Site Inspection of the Subject Property and Rayo Property on behalf of the U.S. EPA Region IX pursuant to the listing of the sites on the Comprehensive Environmental Response, Compensation, and Liability Information System ("CERCLIS") list. The site inspection was completed on 24 May 1994. Bechtel's description of the Subject Property and hazardous substances generated by Webb is summarized as follows.

The Bechtel Report indicated that the equipment storage building on the Subject Property had: "...a hazardous substance storage area attachment on its southeast corner." (Bechtel 1994, page 2)

Related to Webb's operations on the Rayo Property, the report indicated that: "Hazardous substances used in the manufacturing process include solvents, paints, and petroleum-based lubricants. Prior to the mid-1980s, 1,1,1-trichloroethane was used as a solvent to clean fabricated metal pieces. The 1,1,1-trichloroethane was replaced in the mid-1980s with naphtha petroleum, a petroleum-based solvent..." (Bechtel 1994, page 2)

The Bechtel Report summarizes the sources of potential contamination from Webb operations as follows: "A former 8,000-gallon paint and water sump used during the wet-painting process. The sump was converted to hold paint filters for a dry-painting booth in the mid-1980s. Hazardous waste manifests from 1990 through 1993 indicate that fifty 55-gallon drums containing waste paint, used filters, and paint rags were transported off site for disposal..." (Bechtel 1994, page 6)

The 8,000 gallon paint and water sump and a second sump were investigated and closed in accordance with the Los Angeles County Department of Public Works, Environmental Programs Division requirements for underground storage tank closure. A closure approval letter was issued by the County on 17 December 1996. No significant releases were found in this area.

Vision Reports. The Vision reports do not provide chemical use or waste information specifically related to the Subject Property. Before discontinuing operations at the Rayo Property, Webb held South Coast Air Quality Management District Permit No. M58084 for a spray paint booth located on the Rayo Property. Chemical use information for products used at the Rayo Property during 1994 is presented in the appendices of the *Emissions Inventory* report (Vision, 1995). The products were:

- Danger Orange coating (product code 3-WE-2613) manufactured by P.F.I., Inc. Approximately one gallon was used in 1994.

- W/B Acrylic Enamel Safety Yellow coating (product code 728Y047) manufactured by Ellis Paint company. Approximately one gallon was used in 1994.

- W/B Acrylic Enamel Gray coating (product code 728A065) manufactured by Ellis Paint company. Approximately six gallons were used in 1994.

- W/B Acrylic Enamel Blue (Unibilt) coating (product code 728L044) manufactured by Ellis Paint company. Approximately five gallons were used in 1994.

- Cool-Tool II cutting and taping fluid manufactured by Monroe Fluid Technology and Premium AW Hydraulic Oil #32 supplied by Golden West Lubricants, Inc. The combined usage of cutting and hydraulic oils during 1994 is reported to be approximately 30 gallons.

- Rustlick WS-11 manufactured by ITW Fluid Products Group. The approximate quantity used is not reported.

- Kill-Cide 700 manufactured by ITW Fluid Products Group. The approximate quantity used is not reported.

- Solvent 105 supplied by Safety Kleen. Approximately 40 gallons were delivered to the site is 1994.

Uniform Hazardous Waste Manifests. The manifests, along with supporting documentation, indicate the disposition of various hazardous wastes removed from the site(s) by Industrial Waste Utilization, Inc. during March 1996 after Webb closed its operations. Industrial Waste Utilization, Inc.'s job order form indicates that the following wastes were removed and disposed off-site. Most, if not all, of these wastes originated from the Rayo Property.

3 - 55 gallon drums of paint filters
1 - Lot of miscellaneous and 1 gallon containers
1 - 5 gallon pail of sealant
4 - 5 gallon pails of grease
1 - 15 gallon drum of aerosols
2 - 55 gallon drums of water/water based paint
1 - 55 gallon drum of consolidated solvents
2 - 55 gallon drums of rags
1 - 55 gallon drum of paint
several miscellaneous empty drums and containers.

The quantities disposed in March 1996 may not be typical of prior normal operations at the Rayo Property because Webb was in the process of closing down its operations.

According to a regulatory agency database search by Vista Information Solutions, Inc. dated 3 April 1996 ("Vista"), Webb was listed as a large quantity generator of non-acutely hazardous waste with the U.S. EPA's Resource Conservation and Recovery Act Program. This listing is associated with Webb's former operations at the Rayo Property. Webb had EPA Handler I.D. No. CAD008339467.

A.4 Regulatory Agency Information

According to the Vista report, Blake Rivet was listed as a small quantity generator of non-acutely hazardous waste with the U.S. EPA's Resource Conservation and Recovery Act Program. This listing is associated with Blake's former operations at the Subject Property. Blake had Handler I.D. No. CAD063798995.

The Vista report indicates that the Webb site is listed on the CERCLIS database and is under review by the U.S. EPA. Based on the Bechtel report (Bechtel, 1994) it appears that the CERCLIS listing pertains to both the Rayo Property and the Subject Property. The report indicates that further assessment is needed but that the site is considered a lower priority.

EKI contacted the City of South Gate to inquire about the existence of a permit for industrial wastewater discharge for the Subject Property. The City of South Gate file for Industrial Wastewater Discharge Permit No. 5181 indicates that Blake Rivet maintained the permit in connection with its production of aluminum and stainless steel aircraft rivets at the Subject Property. Its wastewater producing operations were sulfuric acid anodizing, tumbling, and deburring. The raw materials used included sulfuric acid, alkaline caustic, and chromic. Approximately 4,000 gallons of wastewater was discharged to the sewer from Blake operations each day. According to a process diagram submitted with the permit application, the anodizing operation included tanks containing the following; sulfuric acid anodize, dichromate seal, DX-34, CH-90 ETCH, and rinse waters. More detailed information describing these solutions was not provided. A spin dryer, vibrator and tumblers were also used in the anodizing area.

A Plumbing Plan submitted with the permit application shows that the wastewater from the anodizing area discharged to a below-ground concrete clarifier located outside the southeast corner of the building. The clarifier consists of three compartments and a sampling box at the point of discharge to the sanitary sewer. According to the Plumbing Plan, the clarifier was approximately 5 feet by 8 feet in area and 3 to 4 feet deep. The Plumbing Plan also indicates that rinse tanks outside the anodizing area may have drained to the clarifier.

A Notice of Violation was issued to Blake on 18 May 1979 by the Sanitation Districts of Los Angeles County for heavy metals discharge. Total chromium was detected at a concentration of 34.3 mg/l in the discharge wastewater from the clarifier. The results of a

subsequent wastewater sample analysis were reported in a Sanitation Districts of Los Angeles County Lab Report No. I-2782 dated 25 July 1979. The following analytical results were reported for the sample collected on 25 July 1979:

COD	105.9 mg/l
Suspended Solids	834.0 mg/l
pH	9.7
total chromium	16.5 mg/l
iron	41.8 mg/l
nickel	0.3 mg/l
oil & grease	7.0 mg/l

In a 27 October 1981 letter from the Sanitation Districts of Los Angeles County, Permit No. 5181 was voided because Blake Rivet was no longer in business. A City of South Gate inspector visited the site on 24 August 1992 and reported that all equipment and floor drains had been removed and that the clarifier had been filled with sand and concrete.

The Plumbing Plan also shows a concrete pit for a furnace and quench tank in an area that appears to be separate from the anodizing operations. The pit had a floor drain that may have discharged to the sanitary sewer. This discharge appears to have been to a separate sanitary sewer line than that of the clarifier. The sewer lines for the quench tank and clarifier apparently connect with a sanitary sewer which crosses through the Subject Property (see Figure 2).

LIST OF TABLES

Introduction

This report presents the methods and results of a soil gas investigation performed December 1 & 2, 1997 at the Jervis B. Webb, Co. facility located at 5030 Firestone Boulevard in Southgate, California by InterPhase Environmental, Inc. (InterPhase) for Erler & Kalinowski, Inc. Soil gas sampling and analyses were performed in accordance with the California Regional Water Quality Control Board - Los Angeles Region (CRWQCB-LA) guidelines for active soil gas investigations under the Well Investigation Program (WIP) revised February 1997.

Background & Theory

Soil gas surveys consist of the sampling and analysis of the soil gases that reside in the pore space of the unsaturated zone above the water table. Because many common organic compounds and industrial solvents exhibit significant vapor pressures and relatively low solubility in water, their introduction into subsurface soils results in vapor phase permeation and transport. Should these chemicals reach the water table and travel with the groundwater, vapors will continue to emanate from the contaminated groundwater into overlying soil. Thus, organic contamination of the subsurface and, possibly, of groundwater can be detected by measuring the concentration of volatile organic compounds (VOCs) in the soil gas.

Whatever the source of the VOC in soil gas, its concentration is representative of soil contamination at the point of measurement. Volatile organic contaminants are present in the gas phase in unsaturated pore spaces, in the water contained in the unsaturated soils, and are adsorbed on the soil particles. The total soils contaminant concentration is the sum of the VOCs contained in the three phases divided by soil mass.

Within the soil volume examined by soil gas sampling, typically less than one cubic foot, equilibrium between the three phases is rapidly attained. The partitioning of the VOCs between gas, liquid and solid phases depends on both the soil properties and the chemical properties of the organic contaminants. Important soil parameters that affect the distribution of VOCs in three phases include the soil's natural and anthropogenic organic content, soil moisture, soil particle size and mineralogy, temperature, lithology, and heterogeneity. Thus, given the chemical properties of the VOC and either measurements or reasonable estimates of relevant soil parameters, soil-gas data can be used to calculate semi-quantitative estimates of soil contamination.

The major uncertainties in estimating soil concentration from soil gas concentration data are the organic and moisture content of the soils. Chemical properties of particular organic compounds are well known, (i.e., vapor pressure, solubility), and the other relevant soil parameters (i.e., bulk density, porosity) have relatively little effect on soil concentration estimates. Use of soil gas to infer concentrations of sources at distance (such as groundwater plumes) is necessarily much more qualitative. Soil gas data used in this manner are limited by the lack of information

regarding the soil parameters interposed between the source and sampling point. It is, therefore, generally not possible to quantitatively estimate groundwater concentrations from soil gas data collected at distance from the saturated interface. Away from source areas (i.e., underground storage tanks, surface spills, etc.) where only the groundwater is providing a significant soil gas concentration, soil gas can be an excellent relative indicator of groundwater contamination. The effectiveness of soil gas surveys to delineate groundwater contamination is variable, however, and depends on the depth to groundwater, contaminant concentration in the groundwater, distribution of air permeabilities in the unsaturated zone, and attenuation of the volatile organics by biodegradation or adsorption.

Scope of Work

This soil gas survey was December 1 & 2, 1997 at the Jervis B. Webb, Co. facility located at 5030 Firestone Boulevard in Southgate, California. InterPhase collected soil vapor samples at depths ranging from two (2) to five (5) feet below ground surface (bgs).

A total of thirty-seven (37) soil gas samples and three (3) duplicate soil gas samples were collected and analyzed on site for this project. This total does not include the two additional samples analyzed as part of the purge volume versus analyte concentration study performed at the first sampling location as required by the WIP. The 2, 4, and 8 purge volume samples collected at location SG-08-5' are labeled A, B, and C, respectively. As a result of this test, eight purge volumes were used for the remaining samples.

December 2, InterPhase sampled location SG-23-5' and collected a sample in a summa canister for analysis via EPA method T0-14 by an off site laboratory to fulfill the analyte confirmation requirement of WIP. The results of this analysis are included in *Appendix D: Analyte Confirmation Sample Results*.

All soil gas samples were analyzed on site for the VOCs listed in Table 1. The analytical results, in micrograms of contaminant per liter of soil gas (µg/L), are included in *Appendix A: Summary of Analytical Results*.

Table 1. Target Analytes

trichlorofluoromethane (F 11)	dichlorodifluoromethane (F 12)
methylene chloride (CH_2Cl_2)	1,1,2-trichlorotrifluoroethane (F 113)
1,1-dichloroethane (1,1-DCA)	vinyl chloride
chloroform ($CHCl_3$)	chloroethane
1,1,1-trichloroethane (1,1,1-TCA)	1,1-dichloroethene (1,1-DCE)
carbon tetrachloride (CCl_4)	cis-1,2-dichloroethene (c-1,2-DCE)
1,2-dichloroethane (1,2-DCA)	trans-1,2-dichloroethene (t-1,2-DCE)
trichloroethene (TCE)	benzene
1,1,2- trichloroethane (1,1,2-TCA)	toluene
tetrachloroethene (PCE)	ethylbenzene
1,1,1,2-tetrachloroethane (1,1,1,2-TCA)	m/p-xylenes
1,1,2,2-tetrachloroethane (1,1,2,2-TCA)	o-xylene

Methods and Instrumentation

Sample Collection

Soil Gas Sampling Apparatus

Soil gas probes were advanced using a Geoprobe® Direct Push Sampling Rig. InterPhase uses the "Post-Run" method of sampling. This means that sample tubing is not carried in the probe rod during probe driving, but rather inserted down the bore once the appropriate sample depth is reached. Sampling probe rod consists of 1 to 2-inch hardened steel. Gas samples are collected from the point holder adaptor mounted on the distal (deep) end of the sampling train. A stainless steel adapter is connected to ¼-inch clean, virgin polyethylene tubing, lowered down the bore of the drive probe string, and mated to the point holder adaptor. O-ring connections enable the system to deliver a vacuum-tight seal to assure that the sample is collected at the bottom. Hamilton or Dynatech 10-cc gas-tight, glass syringes are used to collect soil gas samples.

Pre-Sample Purge

To ensure a representative sample, discrete volumes of gas are purged to rid the tubing of atmospheric air and to allow subsurface air to enter. The volume of gas removed is determined by the volume of tubing employed and the investigative goals of the project. Unlike groundwater sampling, purging of a soil gas probe is designed to remove only the ambient air in the system.

InterPhase scientists have conducted field experiments to estimate the capture zone around the end of the soil gas sampling probe in order to demonstrate that vapor samples are not diluted with atmospheric air. Capture zone estimates are calculated for sandy soils and for silty or clayey soils in the following example:

Sampling Depth: 5 feet (152.4 cm)
Volume of sampling probe (¼ " polyethylene tubing): 5 mL per foot
Purge Volume: 75 mL (Approximately 3 probe volumes - 5' polyethylene tube)

Air porosity of sandy soils: 30% = 0.3
Air porosity of silt or clay soils: 20% = 0.2

Volume of soil gas collected from sandy materials:
75 mL/0.3 = 250 mL

Volume of soil gas collected from silty or clayey materials:
75 mL/0.2 = 375 mL

Assuming isotropic vapor flow, the volume of soil gas collected may be described as a sphere of radius r with the origin at the tip of the soil gas probe. Therefore,

Sand: $(4/3)(\pi)(r^3) = 250$ mL (1mL = $1cm^3$)
$r = 3.9$ cm

Silt/Clay: $(4/3)(\pi)(r^3) = 375$ mL
$r = 4.5$ cm

For this example, the purge volume of 75 mL ensures that three volumes of the sampling apparatus is evacuated (5' polyethylene tubing x 5 mL/foot x 3 purge volumes = 75 mL). The calculated radius of influence, approximately 4 cm, is substantially less than the distance to ground surface (152.4 cm), thus minimizing the potential for sample dilution with atmospheric air.

Sample Analysis

Gas chromatographic techniques were used to identify and measure concentrations of the various compounds. Two electron capture detectors (ECDs), which respond to halogenated organic compounds, are used to quantify most of the halogenated compounds. Each detector has a different column, with different polarity. The first column is a J&W Scientific DB-624. The second is a DB-1. During all analyses the columns are run through a temperature program starting at 55°C, hold for 1.2 minutes, ramp at 10°/minute to 150°C. A photoionization detector (PID), which responds to aromatic organic compounds and some halogenated organic compounds is used to quantify the remaining analytes. During all analyses this column was run through a temperature program starting at 60°C, hold for 1.2 minutes, ramp at 10°/minute to 150°C.

Gaseous standards were used for identification and quantitative measurement of target analytes. The calibration standards were prepared by InterPhase Environmental, Inc., or purchased from Scott Specialty Gases.

Decontamination of Equipment

Sampling equipment is decontaminated by methods consistent with the equipment's use. Sample tubing is used for one sampling event and discarded. Reusable steel parts including adaptors and point holders are cleaned by baking in an oven at 100°C. Syringes are cleaned with Alconox and water and then placed in an oven and heated. Methanol or hexane rinses that can carry contamination, contribute to background, and potentially trap VOCs, are not employed.

Separate storage areas are provided for used and cleaned equipment. The probe rod and drive points are stored in clean storage racks on the sampling rigs. Care is taken with the rods and points to eliminate both soil-surface and cross-hole contamination. No equipment that is in contact with soil gas is used or reused without being decontaminated.

Standards

Neat reagent-grade compounds were used for preparation of stock liquid standards. The stock standard liquid mixture was prepared by adding the desired mass of each compound of interest to a methanol solution. This standard solution is then sealed in single use glass ampules.

For calibration, an ampule was broken open and an aliquot was added to a sealed, nitrogen filled container and heated until the methanol evaporates. This standard gas mixture was then injected into the gas chromatograph (GC) and analyzed to determine the instrument response to each analyte.

Instrumentation

The make and model of the equipment used in the mobile laboratory to perform on-site analyses include:

Varian 3400 Gas Chromatograph;
Hewlett-Packard 5890 Gas Chromatograph;
Varian Electron Capture Detectors;
OI Instruments Photoionization Detector;
J&W Scientific DB-624, 30m Megabore Column;
J&W Scientific DB-1, 30m Megabore Column;
Scientific Software PC-Based Data System.

Quality Assurance / Quality Control

Quality control and quality assurance are achieved through strict laboratory protocol. A system blank was analyzed daily to demonstrate absence of interference in the sampling and analytical systems. An ambient air sample was also analyzed each day to monitor for any possible interference. The ambient air results also help establish background levels and on-site personnel safety.

A three-point curve was generated during the initial calibration of the gas chromatograph. A mid-range calibration check is performed daily to verify instrument response. As required by the WIP QA/QC protocols, the percent relative standard deviation (%RSD) of the mid-point continuing calibration check should be less than 15% except for the freons, vinyl chloride and chloroethane, which must be within 25%.

Response Factors

When the external standard method is used, the computer-integration system calculates response factors (RF) as follows:

$$RF = C/A$$

where C = concentration of analyte in the calibration standard, µg/L
A = area of analyte to be measured

The concentration of the unknowns is determined by comparing the peak area of the unknowns to the peak area of the external standards as follows:

$$C = (A)(RF)$$

where C = concentration of the analyte in sample in µg/L
RF = relative average response factor
A = area of analyte being measured

The practical quantitation limits of reported detection ranged from 0.01 to 1.0 micrograms per liter (µg/L) for all compounds. Higher reporting limits may result from analysis of high concentration samples due to the necessity of using a reduced sample volume or dilutions for analysis. Results of analyses are reported to the nearest µg/L in two significant figures.

Data Interpretation

Vapor-phase diffusion is the prevailing mechanism by which soil gas analytes are transported in the subsurface. The presence of an analyte in soil gas is a function of the phase, location and concentration of the source, physical properties of the analyte, and the media through which transport occurs. The site-specific variability among soil properties profoundly affect vapor-phase diffusion and must be considered in the interpretation of analyte distribution in the soil gas. Among these soil properties are: organic content, soil moisture, soil particle size and mineralogy, and air-filled porosity. Anomalies in the spatial distribution (vertically or laterally) of analyte concentrations in soil gas samples should be noted.

Although isoconcentration contours of soil gas data can be plotted on site maps, it should be emphasized that these isotherms are only representative of the contaminant distribution in soil vapor. Isoconcentration contours for compounds in soil or groundwater may differ in extent and orientation from those delineated in soil gas. Inherent assumptions that are infrequently discussed in preparing soil gas isotherms are:

- Soil gas concentration data are adequate to describe the spatial distribution of contaminants underlying the site
- Vertical anisotropy is either insignificant or can be described by existing site data
- Vapor barriers that may impede the gaseous diffusion of analytes are either nonexistent or do not vary over the investigation site
- Soil texture, water content, and air-filled porosity are spatially uniform over the site

In cases where data values in parts per million by volume (ppm_v) are desired, the conversion of soil gas concentrations from µg/L (gas) to ppm_v can be achieved with the following equation.

$$C_{ppm_v} = \frac{(C_{\mu g/L})(24.1)}{(mw)(P)}$$

Where;

C_{ppm_v}	soil gas concentration in ppm_v
$C_{\mu g/L}$	soil gas concentration in µg/L (gas)
24.1	molar volume at normal room temperature (70°F) in (L)(atm)/mole
mw	molecular weight in grams/mole
P	pressure in atmospheres (typically assumed to be 1 atm)

Using toluene, which has a molecular weight of 92.14, as an example: at normal temperature and one atmosphere of pressure, 1 µg/L of toluene would be equivalent to 0.26 ppm_v.

Table 2 presents the molecular weights that may be used in the above equation to calculate the ppm_v values and reporting limits for the target analytes.

Table 2. Molecular Weights of Target Analytes

Analytes	Molecular Weight
F-12	120.91
F-113	187.38
F-11	137.38
CH_2Cl_2	84.94
1,1-DCA & 1,2-DCA	98.96
$CHCl_3$	119.39
1,1,1-TCA & 1,1,2-TCA	133.41
CCl_4	153.82
TCE	131.39
PCE	165.83
1,1,1,2-TCA & 1,1,2,2-TCA	167.85
vinyl chloride	62.5
chloroethane	64.52
1,1-DCE & c-1,2-DCE & t-1,2-DCE	96.95
benzene	78.12
toluene	92.15
ethylbenzene & xylenes	106.17

Results

Appendix A: Summary of Analytical Results presents the measured concentrations of all samples, blanks, and duplicates analyzed on site during this investigation. Concentrations are reported in micrograms per liter (µg/L) of soil gas.

Due to the wide range of concentrations of TCE and PCE often found in soil gas samples, InterPhase uses two different detectors to quantify these analytes. The ECD is more sensitive and is typically used for low levels of these analytes. When either TCE or PCE is detected at concentrations that exceed the calibrated linear range of the ECD, the PID may be used for quantification rather than diluting and reanalyzing the sample. Diluting samples means fewer samples can be analyzed for a given project and the reporting limits for certain analytes are higher than the 1 µg/L specified in WIP.

All calibration and QA/QC measures are applied to both detectors. When TCE and PCE are detected, a numerical value is entered in the *Summary of Analytical Results* in the appropriate row. A value of NU (not used) is entered in the row next to the detector that was not used to quantify that analyte for that specific analysis.

Appendix B: Quality Control Summary presents the results of the daily mid-level continuing calibration verification standards.

The results of the analyte confirmation sample collected at location SG-23-5' are included in *Appendix D: Analyte Confirmation Sample Results.*

Analyte confirmation analysis as defined by the WIP Guidelines, is meant strictly to confirm the identification of analytes made by a field laboratory (WIP, Section 3.11). Results from the analysis of the confirmation sample collected at SG-23-5' indicate both laboratories were in agreement with the compounds identified in this sample.

InterPhase and EAS each reported 1,1,1-trichloroethane (111-TCA), trichloroethene (TCE), and tetrachloroethene (PCE) at this sample location.

EAS detected dichloromethane (methylene chloride, CH_2Cl_2) toluene, styrene, and xylenes in this sample. Styrene was not among the target analytes for the mobile laboratory for this project. The toluene and xylene concentrations were below InterPhase's reporting limits for these compounds.

This data indicates that the confirmational sample achieved it's goal of confirming the compound identification of InterPhase's mobile laboratory. Though not a specific goal of this test, the numerical results can be compared. To convert the EAS results from $\mu g/m^3$ to $\mu g/L$, divide by 1000. When this is done, the results show InterPhase's results differ from EAS's by the following ratios: 111-TCA (low by a factor of 4.2), TCE (low by a factor of 1.4), and PCE (low by a factor of 2.7). The immediate reasons for the differences are not known, but may be attributable to one or more of the following: chemical and physical properties of the specific analytes, chemical and physical properties of the subsurface, differences in sample collection methods, sample volume, sampling rate, applied vacuum during sampling, sample holding time and analytical methods.

Site Name:	JERVIS B. WEBB CO.
Location:	9301 RAYO SOUTH GATE, CA
Dates Worked:	12-1-97 → 12/2

Logbook # 1 of 1

Project Summary

Total Number of Soil Gas Samples Collected	37 + 2 P.V.T. + 3 dup
Total Number of Soil Samples Collected	Ø
Total Number of Groundwater Samples Collected	Ø

List of Materials Lost or Damaged on Project

Ø

Expendable Materials Used on Project:

Expendable Drive Points (#): 43	Poly tubing (ft): 185'
Bentonite (# bags): 3	Cement/Asphalt Patch (# bags): 1 cement ½ Asphalt
Other Expendables: Ø	Rental Equipement: Ø

Notes of Interest

1 Suma for TO-14

Project Background Information

Project No.: 97119	Phase No.: 3
Site Name: IRVIS B. WEBB CO.	Location: SOUTHGATE, CA
Dates Worked: 12-1-97 →	
Client Name and Address: EPLER & KALINOWSKI 2951 28TH STREET, SUITE 1020 SANTA MONICA, CA 90405	Client Field Representative(s) Name(s): ROB
Client Telephone: 316-314-8855	Client FAX:
Crew	
Chemist: TANGEMAN	Technician: FAVERO

Additional information to be included with data report at Client's request:

Purpose of Investigation:
to determine if there are any off-site sources

Target VOCs:

WIP

Groundwater Information (if available):

Depth to Groundwater: ~ 40'-50' Direction of Flow:

Possible/Known Source(s) of Contamination (if available):
— RIVET MANUFACTURER. CLARIFIER

Subsurface Conditions (Soil Type, Subsurface Geology, etc.)

If maps are required, draw to scale and include: Project Number, Client, Site Name and Location, Scale (both bar and inch equivalent), North Arrow (approximate), Sampling Locations and Numbers.
If maps are supplied by client, check for accuracy and clarity and enclose.

Daily Summary

Date: 12-1-97	Project No.: 97119
Client: ERLER	
Weather: SUNNY HIGH 65° LOW 50°	

Field Hours

Time on Site: 0700	Lunch Hours: 1 Hour
Time off Site: 1715.	Downtime Hours: 0
	Standby Hours: 0

Calibration

Start Calibration:	0700	
Stop Calibration:	0800	
Total Calibration Hours:	1	

Sample Summary

Total Syringe/System Blanks: 1	Total Ambient Air Blanks: 1
Total Soil Gas Samples: 32 + PURGE	Total Soil Samples: 0
Total Groundwater Samples: 0	Other (specify): 6

Backfill Procedures Used: — BENTONITE	Decon Procedures Used: — DISCARD TUBING & BAKE PT. HOLDER

Expendables

Expendable Drive Tips Used: 23	Poly Tubing (ft.) Used: 100'
Bentonite Used (# bags): 2 BAGS	Cement Used (# bags): 0
Asphalt Used (# bags): 1/4	

List Equipment Lost or Damaged — NONE

Rental Equipment Used: — NONE

Analyte Confirmation
Sample Results

December 16, 1997
Sample Delivery Group (SDG): 70551

Scott Norris
InterPhase Environmental
6200 Peachtree Street
Los Angeles, CA 90040

Dear Scott:

Enclosed is the analytical report for the samples received and analyzed by Environmental Analytical Service, Inc. for the following project:

Project Name: Jervis B. Webb
Project Number: 97119

The report consists of the following sections:

I. Sample Description
II. Laboratory Narrative and Chain of Custody Forms
III. Laboratory Certification
IV. Quality Control Reports
V. Analytical Results

If you have any questions on the report or the analytical data please contact me at (805) 781-3585.

Sincerely,

Steven D. Hoyt, Ph.D.
Laboratory Director

Analytical Report

SDG Number 70551

Client: InterPhase Environmental **Date Received:** 12/3/97

I. SAMPLE DESCRIPTION AND ANALYSIS REQUESTED

Client Sample No.	EAS Lab No.	Analysis Requested	Date Sampled	Pressure (torr) Rec	Final
SG-23-5'	70551 1	EPA TO-14 Volatile Organics	12/2/97	722	904

II. LABORATORY CASE NARRATIVE and CHAIN OF CUSTODY FORMS

SDG Number: 70551
Analysis performed for: InterPhase Environmental

All laboratory quality control criteria were met for the samples in this report except chlorobenzene exceeds the QC limits for the duplicate spike analysis.

III. LABORATORY CERTIFICATION

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the condition noted above.

Steven D. Hoyt, Ph.D.
Laboratory Director

Client: InterPhase Environmental

LABORATORY QC REPORT

QC NARRATIVE

This report was run with the standard laboratory QC.

STANDARD LABORATORY QC REPORT

Unless project specific QC was requested, this Section contains the standard laboratory QC supplied with the analytical reports, which includes the daily method blank and the daily duplicate control samples as described below. Each day that samples are analyzed comprises a Daily Analytical Batch for a particular instrument. A Daily Analytical Batch QC report will be supplied for each method and each day samples from this SDG Group were analyzed.

METHOD BLANK

A method blank is a laboratory-generated sample which assesses the degree to which laboratory operations and procedures cause false-positive analytical results for your samples. A copy of the batch blank is included with the report.

DUPLICATE CONTROL SAMPLES

A duplicate or duplicate control sample (DCS) was analyzed as part of each daily analytical batch. A DCS is a well-characterized matrix (blank water, ambient air, or actual sample) which may or may not be spiked and run in duplicate with your sample batch. The results are on the attached Duplicate Sample/Spike results. Precision is measured in a duplicate test by Relative
Percent Difference (RPD) as in:

$$RPD = \frac{[\%\ \text{Recovery Test 1} - \%\ \text{Recovery Test 2}] \times 100}{(\text{Recovery Test 1} + \text{Recovery Test 2}) / 2}$$

V. ANALYTICAL RESULTS

SDG Number: 70551
Client: InterPhase Environmental

The following pages contain the certified reports for the analytical methods and the compounds requested. The reports are in order of analytical method then EAS ID number. A brief description of the units that appear on the reports is given below:

ppbV, ppmV, Percent

Parts per billion by volume (also known as mole ratio) and other related units. This is the primary reporting unit for all volatile organic compound analysis except the hydrocarbon speciation and total hydrocarbons. This unit is independent of temperature and pressure.

$$\text{ppbV} = \frac{\text{nanomoles of compound}}{\text{moles of air}}$$

ug/m3, mg/m3

Micrograms of compound per cubic meter of air and other related units. This is the primary reporting unit for semi volatile organic compounds. It is not a primary reporting unit for volatile organic compounds because it is temperature and pressure dependent, so the result will vary depending on the conditions when the sample was collected. EAS provides the units on its analytical reports as a convenience to the client, but they should be used with caution. The following equation can be used to convert from ppbV to ug/m3.

$$\text{ug/m3} = \frac{\text{ppbV x MW compound}}{23.68}$$

23.68 is the molar volume of a gas at 60 F and 1 atm pressure

ppbC, ppmC

Parts per billion by volume as carbon (methane) and other related units. This unit is the primary reporting unit for hydrocarbon analysis, even if it does not appear on the report. This unit is used because the flame ionization detector response is proportional to the number of carbons in the compound, so an accurate concentration can be reported even if the identification of the compound is not known.

$$\text{ppbC} = \text{ppbV x number of carbons in compound}$$

Form I-AAVC

DATA QUALIFIERS AND ABBREVIATIONS

ENVIRONMENTAL
Analytical Service, Inc.

*	See case narrative
B	This compound was also detected in the blank
D	This report was calculated from a secondary dilution factor
E	Compound exceeds the calibration range and is an estimated value
J	The amount reported is an estimated value as it is below the reported MDL
F	Higher detection limit due to sample matrix
G	Higher detection limit due to limited sample size
Q	Compound ion ratio qualifiers are outside the standard acceptance criteria
R	Compound retention time (RT) is outside the acceptance criteria for the method
MDL	Minimum Detection Limit - Instrument detection limit

The minimum detectable level (MDL) is the lowest concentration of a substance that can be measured with confidence. The MDL is calculated at the 99% confidence level from seven repetitive measurements on a sample whose concentration does not exceed 10 times the estimated MDL (Glasser et. al. 1981; Long and Winefordner, 1983). In generating an MDL study, a sample is prepared in the appropriate matrix with components near the estimated MDL which is about 3 times the instrument noise level. This sample is run seven consecutive times and the standard deviation (S) is calculated. The MDL is determined using the following formula:

MDL = 3.14*S.

ND	Not Detected - a reported limit
NA	Not Applicable
RPD	Relative Percent Difference

The relative percent difference for a pair of duplicate samples is calculated from repetitive runs on sample pairs representative of the types of samples that are analyzed. The RPD provides information on the precision or reproducibility of the actual measurement process. The RPD is calculated for a particular compound from the average using the following equation:

$$RPD(\%) = \frac{\text{Difference} * 100}{\text{Average}}$$

RSD	Relative Standard Deviation

The relative standard deviation is reported as a percentage deviation at a particular concentration using the following equation:

$$RSD(\%) = \frac{S * 100}{\text{Ave.}}$$

DEFINITIONS

ppbV $= \frac{\text{\# nanomoles cmpd}}{\text{\# moles air}} = \frac{\text{ppbC}}{\text{\# carbons in cmpd}}$

Compound is reported as ppb of compound by Volume

This unit is temperature independent

ug/m^3 $= \text{ppbV} \times \frac{\text{MW compound}}{23.68}$

Compound is reported as ug of a compound in a m^3 of air

23.68 is the molar volume of a gas at 60° F and 1 atm pressure

MW = molecular weight

This unit is temperature dependent

ppbC = ppbV x # carbons in compound

FACSIMILE TRANSMISSION COVER SHEET

DATE: October 29, 1997 CONTRACT NO: 961025.02

SUBJECT: REVISED Additional Analysis Request for Samples from 5030 Firestone Blvd, South Gate

Total Pages with Cover Sheet: 1

TO: Marie / Mark Noorani
Orange Coast Analytical
3002 Dow, Suite 532
Tustin, CA 92680

Fax No: (714) 832-0067

FROM: Steve Miller
EKI Santa Monica

REMARKS Please perform the following additional analyses for samples collected from 5030 Firestone Boulevard on October 28, 1997

Sample No.	Analyses Requested
B4 - 16	CCR Title 22 Metals
B5 - 6	pH
B6 - 6	pH
B7 - 6	pH
B8 - 6	pH
B10 - 6	CCR Title 22 Metals

Please call with any questions. Thank you

LABORATORY REPORT FORM

Laboratory Name: Orange Coast Analytical

Address: 3002 Dow Suite 532 Tustin, CA 92780

Telephone: (714) 832-0064

Laboratory Certification
(ELAP) No.: 1416 Expiration Date: 1999

Laboratory Director's Name (Print): Mark Noorani

Laboratory Director's Signature: Mark Noorani

Client: Erler & Kalinowski, Inc.
Project No.: 961025.00
Project Name: Webb
Laboratory Reference: EKI 9783

Analytical Method: 8010

Other

Date Sampled: 12-02/03-97
Date Received: 12-05-97
Date Reported: 12-12-97

Sample Matrix: H20
Extraction Method: n/a
Extraction Material: n/a

Chain of Custody Received: Yes X
Sample Condition: Chilled

-- Sample Headspace Description (%): 0
-- Sample Container Material: Brass

FIRM NAME: Orange Coast Analytical

TELECOPIER NUMBER OF ADDRESSEE: 714-434-0067

FROM: Rob Hesse

TOTAL NUMBER OF PAGES TRANSMITTED INCLUDING COVER SHEET: 1

PROJECT: Webb PROJECT NUMBER: 961025.02

WE ARE SENDING YOU A COPY OF:

( ) Report
( ) Letter/Memorandum
( ) Specifications
( ) Other

DESCRIPTION:

Reporting information for 8010 analyses of samples collected on 12/02/97 and 12/03/97.

THESE ARE TRANSMITTED AS CHECKED BELOW:

( ) As Requested
( ) For Approval
( ) For Review and Comments
( ) For Information and Coordination

REMARKS:

Please report results of analyses with the following sample identification number change:

Change boring ID Number B-#-# to the format B#-# using the same ID numbers as indicated by the samples (e.g. B-14-10 will be reported as sample number B14-10). Many thanks.

RE: LABORATORY TEST RESULTS/REPORT
Project Name: Webb
Project No.: 961025.02
EGL Job No.: 97-065-001

Gentlemen:

We have completed the testing program conducted on samples from the Webb project. The tests were performed in accordance with testing procedures as follows:

TEST	METHOD
Air Permeability	API RP40
Moisture Content & Density	ASTM D2937
Total Organic Carbon	Walkley-Black

Enclosed is the Summary of Laboratory Test Results. The invoice for services provided is also included.

We appreciate the opportunity to provide testing services to Erler & Kalinowsky, Inc. Should you have any questions, please call us.

Sincerely yours,

Jack C. Lee, PE, GE
